

Package ‘LDJump’

July 10, 2017

Type Package

Title Estimating Variable Recombination Rates from Population Genetic Data

Version 0.1.0

Depends R (>= 2.10), adegenet (>= 2.0.1), ape, genetics (>= 1.3.8.1), Biostrings (>= 2.38.4), stepR, seqinr (>= 3.1-3), quantreg, vcfR (>= 1.5.0)

Author Philipp Hermann

Maintainer Philipp Hermann <philipp.hermann@jku.at>

Description This package estimates variable recombination rates from population genetic data. It is a unix based program (with a necessary installation of LDHat), able to estimate the recombination map of sequences in fasta and vcf format. Sequences are divided in segments of user defined length. The recombination rate is estimated for every segment with a regression model. This set of estimates is fed in a segmentation algorithm (SMUCE) to estimate the breakpoints of the recombination landscape.

fgt_rrate_dpr

*Four Gametes Test, R^2 and LD' Calculation***Description**

This helper function calculates three summary statistics of the regression model. Here, the four gametes test, R^2 , and LD' are calculated for each pair of sites and returned to its calling function (summary_statistics)

Usage

```
fgt_rrate_dpr(x, y, data1, data2)
```

Arguments

x	Site 1
y	Site 2
data1	Data set to calculate the first two summary statistics
data2	Data set to calculate the four gametes test

Value

A vector is returned containing three values for:

fgt	An indicator value whether the four gametes test indicates a recombination event
R^2	for the pair of sites x and y using diseq, genotype
LD'	for the pair of sites x and y using diseq, genotype

```

get_smuce	<i>Segmentation Algorithm to Estimate Breakpoints in the Recombination Map</i>
-----------	--

Description

First, the recombination rates per segment are computed based on the regression model (generalized additive models) as well as the bias correction. Consequently, we apply SMUCE (simultaneous multiscale change-point estimator) of Frick (2014) and Futschik et al. (2014) to estimate locations and breakpoints in the recombination map. Under a specific type-I error probability α the number of distinct segments with respect to the recombination rate is not overestimated.

Usage

```
get_smuce(help, segs, alpha, ll, quant = 0.35, rescale = F)
```

Arguments

help	a matrix containing a set of summary statistics is calculated in the function <code>summary_statistics</code> . These values are used in the regression model to calculate the (constant) recombination rates.
segs	A (non-negative) integer which reflects the number of segments considered. It is calculated in the program based on the user-defined <code>segLength</code> .
alpha	A value from the interval (0,1) for the type-I error probability used in the segmentation algorithm. We recommend to use 0.05.
ll	A (non-negative) integer which reflects the total sequence length of the sequences under study.
quant	A value between 0.1 and 0.5 with 0.05 distances in between which reflects the quantile used in the quantile regression. We recommend to use the 0.35 quantile.
rescale	a optional logical value: if <code>TRUE</code> , it rescales the sequence length of the output of SMUCE to a range from 0 to 1.

Value

<code>seq.full.cor</code>	The final estimate of the recombination map. Depiction with plot-function of <code>stepR</code> package.
<code>pr.full.cor</code>	A vector of (constant) estimates of the recombination rate per segment.

LDJump

Estimate Variable Recombination Rates from Population Genetic Data

Description

This function estimates variable recombination rates from population genetic data. Therefore, a segmentation algorithm with specific segment lengths (`segLength`) and under a type-I error probability (`alpha`, α) is applied. The returned object can be plotted with the `plot`-function of the package `stepR`.

Usage

```
LDJump(seqName, alpha = 0.05, segLength = 1000, pathLDHat = "",
       format = "fasta", refName = NULL, start = NULL)
```

Arguments

<code>seqName</code>	A character string containing the path and the name of the sequence file in <code>fasta</code> or <code>vcf</code> format.
<code>alpha</code>	A value from the interval (0,1) for the type-I error probability α used in the segmentation algorithm. We recommend to use 0.05.
<code>segLength</code>	A integer value for the length of the segments, provided by the user. The default value of 1000 is our recommended value (1kb). The number of resulting segments, based on the sequence length is calculated within the function.
<code>pathLDHat</code>	A character string containing the path to <code>LDHat</code> . This path and the installation of <code>LDHat</code> is necessary for the computation of the package.
<code>format</code>	A character string which can be either <code>fasta</code> or <code>vcf</code> . If <code>fasta</code> , the package will proceed with the computation of the recombination map. If <code>vcf</code> , the package will convert the data in <code>vcf</code> format to <code>fasta</code> format with the function <code>vcfR_to_fasta</code> and then proceed as in case <code>fasta</code> .
<code>refName</code>	An (optional) path to the reference sequence for the region of interest downloaded from e.g. http://phase3browser.1000genomes.org/index.html . Only to be used in case that <code>format == "vcf"</code> .
<code>start</code>	An (optional) integer value which reflects the starting position of the sequences in bp. Only to be used in case that <code>format == "vcf"</code> .

Value

A list is returned which contains the following arguments:

<code>seq.full.cor</code>	The final estimate of the recombination map. Depiction with plot-function of stepR package.
<code>pr.full.cor</code>	The (constant) estimates of the recombination rate per segment.
<code>help</code>	A helper matrix containing the summary statistics per segment used in the regression model.
<code>alpha</code>	The type-I error probability α
<code>nn</code>	The number of individuals (more precisely sequences) for which the recombination map was estimated.
<code>ll</code>	Total sequence length
<code>segs</code>	The number of segments by which the sequence is divided. Resulting from the user-defined segment length (<code>segLength</code>).

Note

This function only works with unix and having **LDHat** (Auton and McVean (2007)) installed. Please properly check all paths to **LDHat** as well as the sequence files. The required lookup tables used by **LDHat** should be located in the path "pathToLDHat/LDhat-master/lk_files". Lookup tables are contained in LDHat, but we also provide several lookup tables at [TBA:urltoGithub](#).

list.quantile.regs	<i>Quantile Regressions for Bias Correction</i>
--------------------	---

Description

This data set contains a list of quantile regression models ([rq](#)) for bias correction. In total nine regression models are saved in a list form, where we recommend to use the 0.35 for the correction.

Usage

```
data("list.quantile.regs")
```

Format

A list object of length 9, containing quantiles in sequences between 0.1 and 0.5 with 0.05 distances.

Examples

```
data(list.quantile.regs)
##### Do not run these examples #####
##### In get_smuce the function is called as follows #####
##### pr1 = predict(mod.full,help); pr1[is.na(pr1)] = -1/gam; #####
##### ind.q = which(seq(0.1, 0.5, by = 0.05) == quant) #####
##### pr.cor = predict(list.quantile.regs[[ind.q]], data.frame(x = pr1) #####
```

mod.full	<i>Regression model to Estimate (constant) Recombination Rates from Population Genetic Summary Statistics</i>
----------	---

Description

This data set contains a generalized additive regression model ([gam](#)) which estimates the constant recombination rate for a set of segments based on summary statistics.

Usage

```
data("mod.full")
```

Format

A list containing all information on the regression model such as the coefficients, residuals, among others as usually for generalized additive models ([gam](#)) saved as an R object.

References

```
data(mod.full)
##### Do not run these examples #####
##### In get_smuce the function is called as follows #####
##### pr1 = predict(mod.full, help) #####
```

summary_statistics *Summary Statistics per Segment*

Description

This function computes summary statistics for every segment of the sequence. Sequence files are generated within this function which are then used by [LDHat](#) and other packages to estimate all necessary parameters.

Usage

```
summary_statistics(x, s, segs, seqName, nn, ll, thth = 0.005,
                  cor = 1, pathLDHat)
```

Arguments

x	A integer control variable for the considered segment of the DNA sequence.
s	An XStringSet object which is read by readDNAStringSet
segs	A (non-negative) integer which reflects the number of segments considered. It is calculated in the program based on the user-defined segment length.
seqName	A character string containing the path and the name of the sequence file in fasta or vcf format.
nn	An integer which reflects the number of individuals (more precisely sequences) of the population to be analyzed. In case of diploid samples this is twice the number of individuals.
ll	A (non-negative) integer which reflects the total sequence length of the sequences under study.
thth	A numeric value for Wattersons θ used in the lookup tables of LDHat .
cor	A integer value which reflects the number of cores on which LDHat should be run. We recommend to keep here 1 core.
pathLDHat	A character string containing the path to LDHat . This path and the installation of LDHat is necessary for the computation of the package.

Value

This function returns a concatenated vector of two separately used vectors (scalars) of summary statistics as:

stats	A vector of summary statistics. Returned with the value of hahe .
hahe	The haplotype heterozygosity of the considered segment. Returned with stats.

vcfR_to_fasta

Conversion of vcf to fasta Format

Description

This function enables to read vcfR files and convert them to necessary fasta files. Therefore, we recommend to provide a reference sequence from e.g. genome browser and the starting position. The default parameters are those of the vcfR package.

Usage

```
vcfR_to_fasta(seqName, refName = NULL, ext.ind = T, cons = F,
              ext.haps = T, start = NULL)
```
